1.1.1. Calculate Momentum

12:24

Write a program that accepts the mass of an object (in kilograms) and its velocity (in meters per second), then calculates and displays the momentum of the object. The momentum is calculated using the formula: where: m is the mass of the object (in kilograms). v is the velocity of the object (in meters per second).

Input Format:

A single floating-point number representing the mass of the object in kilograms.

A single floating-point number representing the velocity of the object in meters per second.

Output Format:

The output will display calculated momentum with appropriate units (kgm/s) (rounded up to 2 decimal places).

Code:

```
m = float(input()) v =  
float(input()) p = m * v  
print(f"{p:.2f}",end="")  
print("kgm/s")
```

1.1.2. Conditional Calculation Based on the Number of Digits

14:30

Write a Python program that accepts an integer as input. Depending on the number of digits in .

Constraints:

$$1 \leq \leq 999$$

Input Format:

The input consists of a single integer .

Output Format:

If is a single-digit number, print its square.

If is a two-digit number, print its square root (rounded to two decimal places).

If is a three-digit number, print its cube root (rounded to two decimal places).

Else print "Invalid".

Code:

```
n = int(input()) if
```

```
1<= n and n<10:
```

```
    print(n*n)
```

```
elif 10<=n and n<100:
```

```
    print(f"{n**(1/2):.2f}")
```

```
elif 100<=n and n<1000:
```

```
    print(f"{n**(1/3):.2f}")
```

```
else:
```

```
    print('Invalid')
```

1.1.3. Days between Two Dates

31:00

Write a Python program to calculate number of days between two dates.

Input Format:

The first line contains the first date in the format .

The second line contains the second date in the format .

Output Format:

An integer representing the number of days between the given dates.

Note:

The first date should always be considered earlier than the second date.

Code:

```
from datetime import datetime d1
=datetime.strptime(input(), "%Y-%m-%d") d2
=datetime.strptime(input(), '%Y-%m-%d')
print((d2-d1).days)
```

1.1.4. Reverse a Number

23:03

Write a Python program to reverse the digits of the number and print the reversed number.

Input Format:

The input is a single integer.

Output Format:

The output prints a single integer, which is the reversed number.

Code:

```
n=int(input())  
reversed__numnum = int(str(n)[::-1]) print(reversed__numnum)
```

1.1.5. Multiplication Table

02:55

Write a Python program that takes an integer as input and prints the multiplication table for that integer from 1 to 10.

Input Format:

The first line of input contains an integer that represents the number for which the multiplication table is to be printed.

Output Format:

Print the multiplication table for the given number in the format:

<number> x <multiplier> = <result>

Note:

The character "x" is used in the output to represent multiplication.

Refer to the visible test-cases for more clarity.

Code:

```
n = int(input())  
for i  
in range(1,11):  
    print(f"{n} x {i} = {n*i}")

1.2.1. Pass or Fail

07:10

Write a Python program that accepts the number of courses and the marks of a student in those courses.

The grade is determined based on the aggregate percentage:

If the aggregate percentage is greater than 75, the grade is Distinction.

If the aggregate percentage is greater than or equal to 60 but less than 75, the grade is First Division.

If the aggregate percentage is greater than or equal to 50 but less than 60, the grade is Second Division.

If the aggregate percentage is greater than or equal to 40 but less than 50, the grade is Third Division.

Input Format:

The first input will be an integer , the number of courses.

The second input will be integers representing the marks of the student in each of the courses, separated by a space.

Output Format:

If the student passes all courses:

Print the aggregate percentage (formatted to two decimal places).

Print the grade based on the aggregate percentage.

If the student fails any course (marks < 40 in any course), print:

"Fail".

Note:

Aggregate Percentage: Average performance across all courses, calculated by summing all marks and dividing by the **number of courses**.

Code:

```
num_courses):
```

```
    total_marks = sum(marks)
```

```

    aggregate_percentage = (total_marks / (num_courses * 100)) * 100
if any(mark < 40 for mark in marks):
    return "Fail"

if aggregate_percentage > 75:
    grade = "Distinction"
elif aggregate_percentage >= 60:
    grade = "First Division"
elif aggregate_percentage >= 50:
    grade = "Second Division"
elif aggregate_percentage >= 40:
    grade = "Third Division"

return round(aggregate_percentage, 2), grade

num_courses = int(input( ))
marks = list(map(int, input().split()))

result = calculate_grade(marks, num_courses)

if result == "Fail":
    print("Fail")
else:
    aggregate_percentage, grade = result
    print(f"Aggregate Percentage: {aggregate_percentage:.2f}")
    print(f"Grade: {grade}")

1.2.3. Pattern - 1

02:30

Write a Python program to print a pattern of asterisks in the form of a right-angled triangle.

Input Format:

The input is an integer, representing the number of rows in the pattern.

Output Format

The output should display the pattern of asterisks (*), with each row containing an increasing number of asterisks.

Note: Refer to the displayed test cases for the sample pattern.

Code:

```
n = int(input())  
def  
ster(n):  
    for i in  
range(1, n + 1):  
        print("* " * i)
